# Outline

**Motivation**

**Experiment**

**Modeling and Results**

**Discussion and Future Plans**

## Motivation

ICRH – heated ELMy plasmas are suggested for reactor startup

But NB-heated ELMy plasmas have better diagnostics and better performance in present-day experiments

To what extent are NB and ICRH ELMy's comparable?

### Goals

Compare global and local parameters for ICRH and NBI ELMy's

Compare results with Ion Temperature Gradient theory

## Results from experiment

Matched pair of ICRH and NBI heated ELMy plasmas

Heating power lower than desired (close to L-mode)

$V_{\text{Tor}}$  for RF in Co- $I_p$  direction, similar in shape to that of NBI, but 15% magnitude

Power deposition in ICRH more central, similar to that expected by alpha heating

Higher central  $Z_{\text{eff}}$  with ICRH

## Results from theory

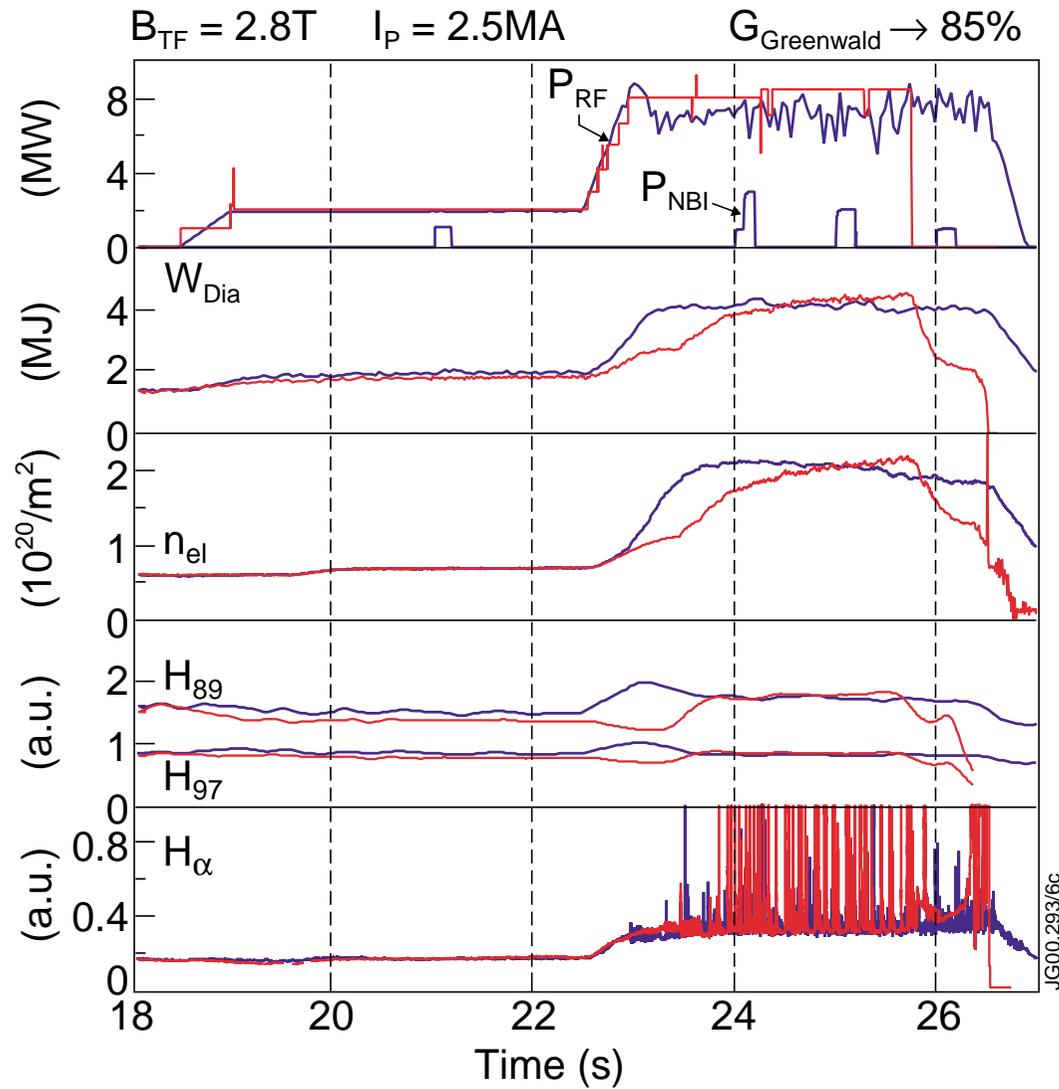

Near the mid-radius,  $R/L_{Ti}$  close to  $R/L_{\text{crit}}$  for ICRH and NBI

Peak  $\gamma_{\text{lin}}$  similar for ICRH and NBI

Peak  $\omega_{\text{ExB}}$  and  $\omega_{\text{ExB}} / \gamma_{\text{lin}}$  smaller for ICRH

## Matched pair of plasmas:

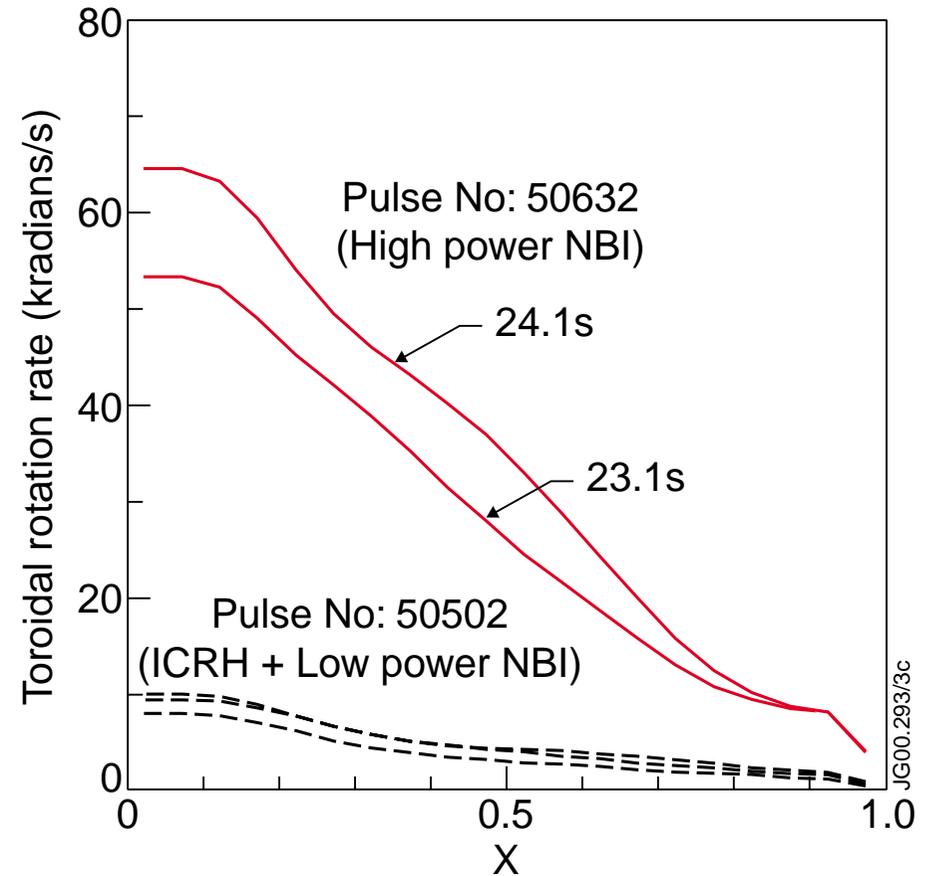

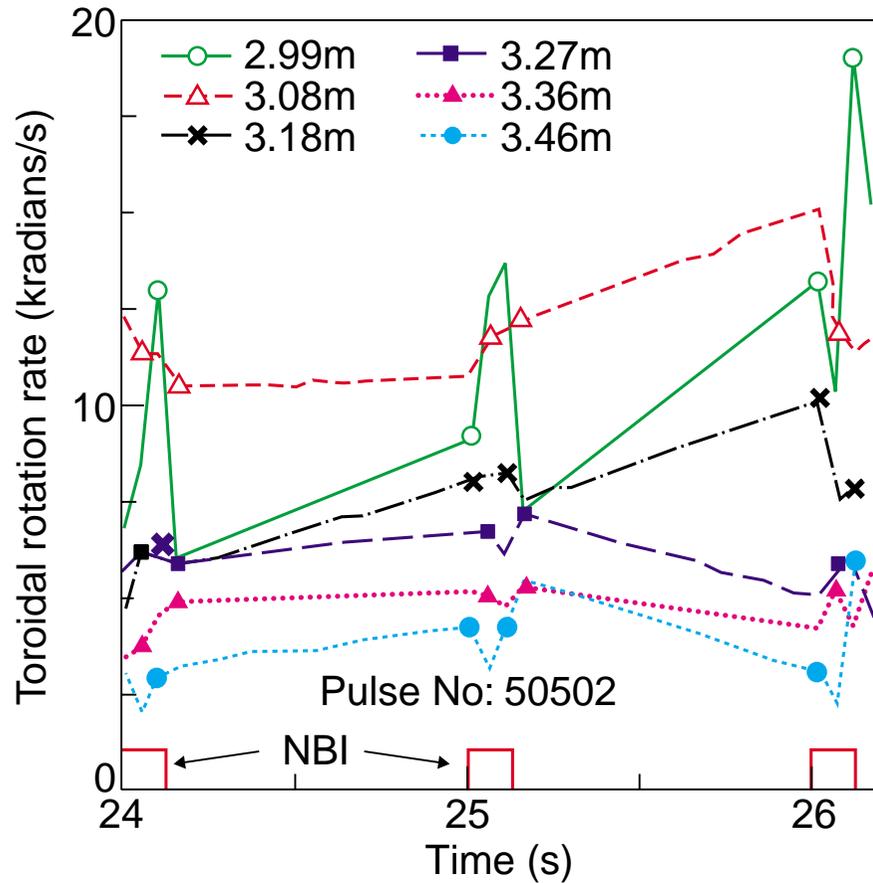

Pulse No: 50502 with ICRH

Pulse No: 50632 with NBI

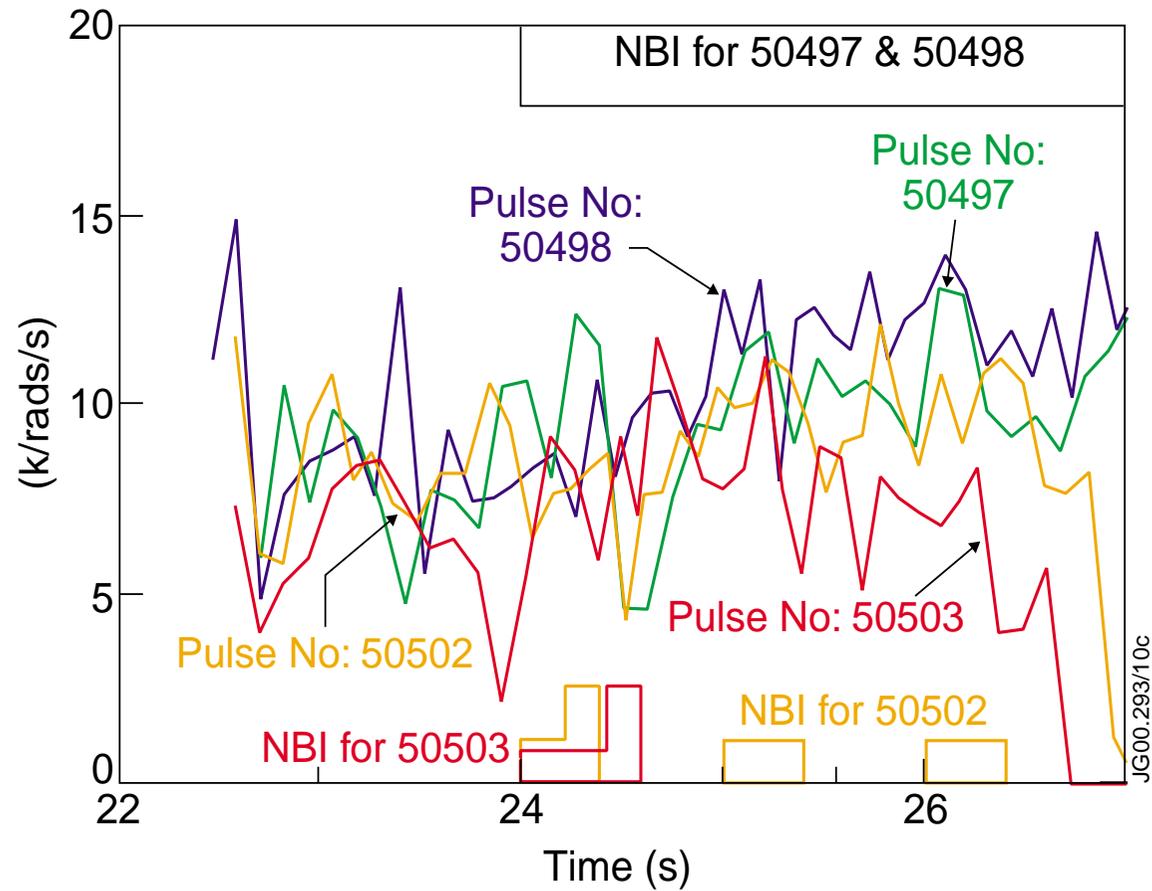

## Measured toroidal rotation rate from CX

Rotation factor of 6 lower with ICRF

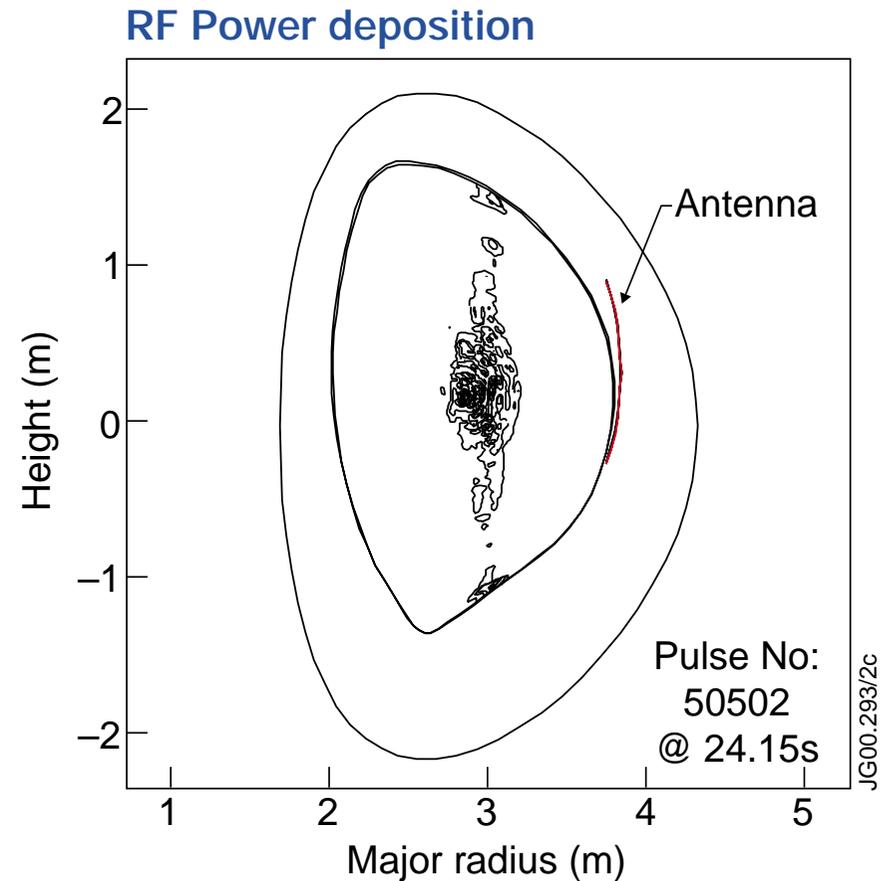

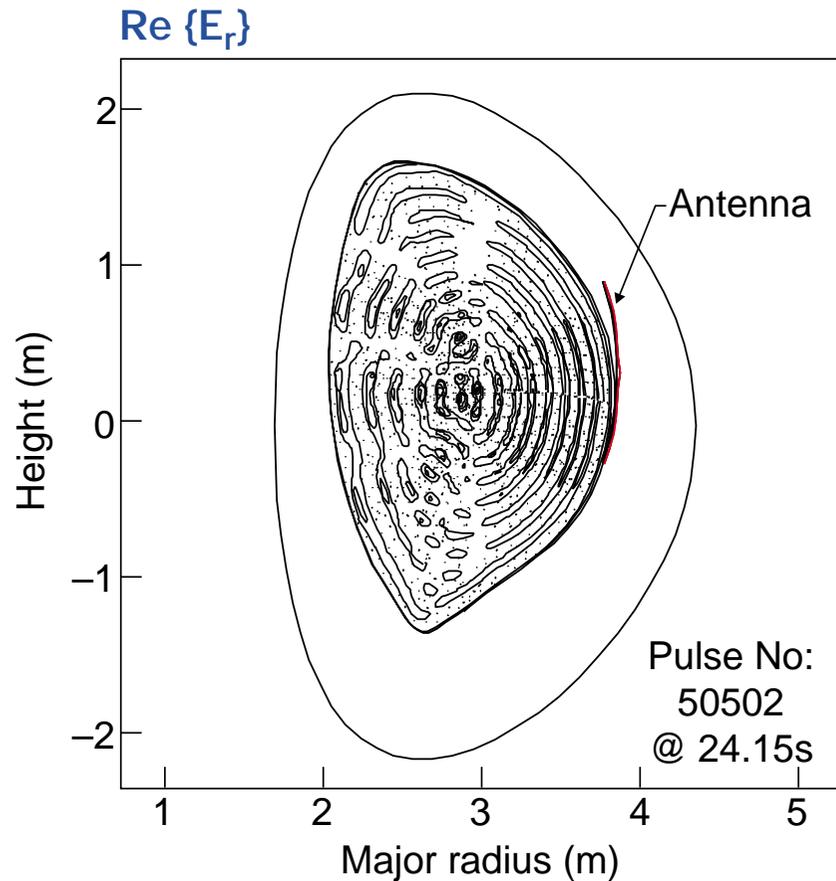

## Toroidal rotation rate measurements of Ni27 consistent with CX measurements

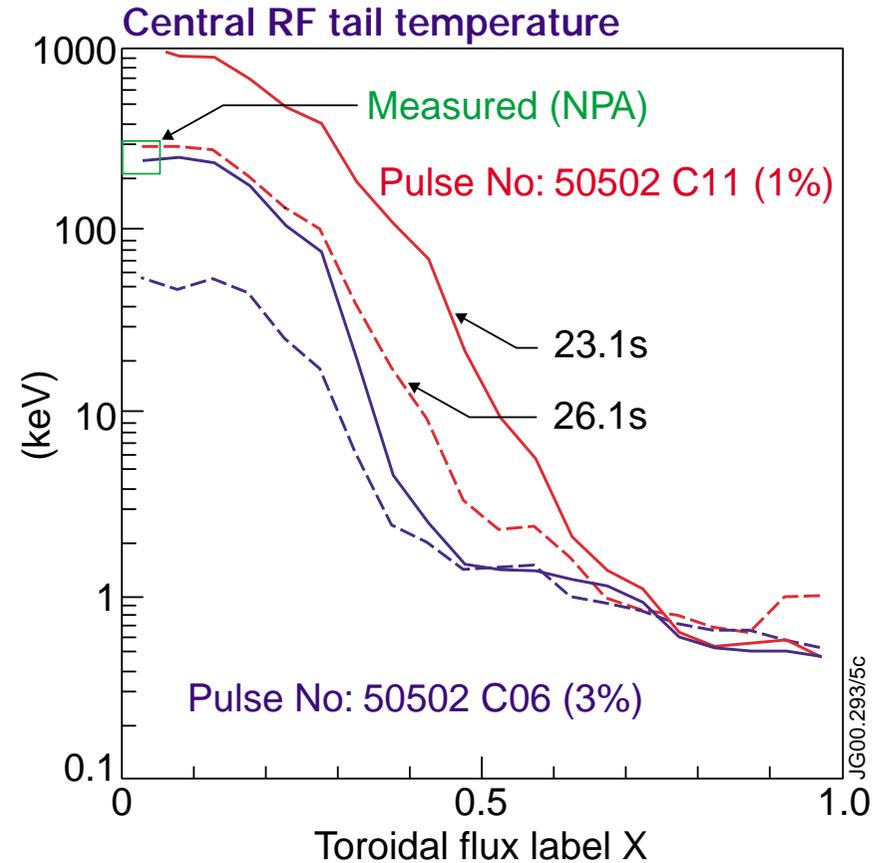

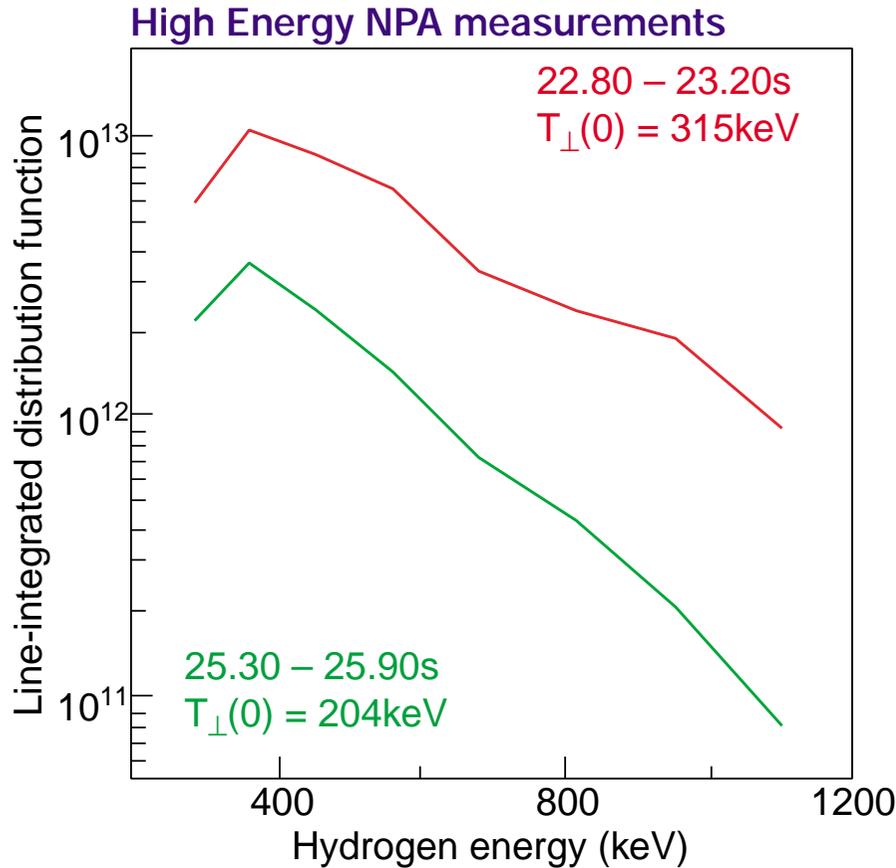

## 2D contours from TRANSP using SPRUCE ICRH model

Well focused heating on resonance rear axis

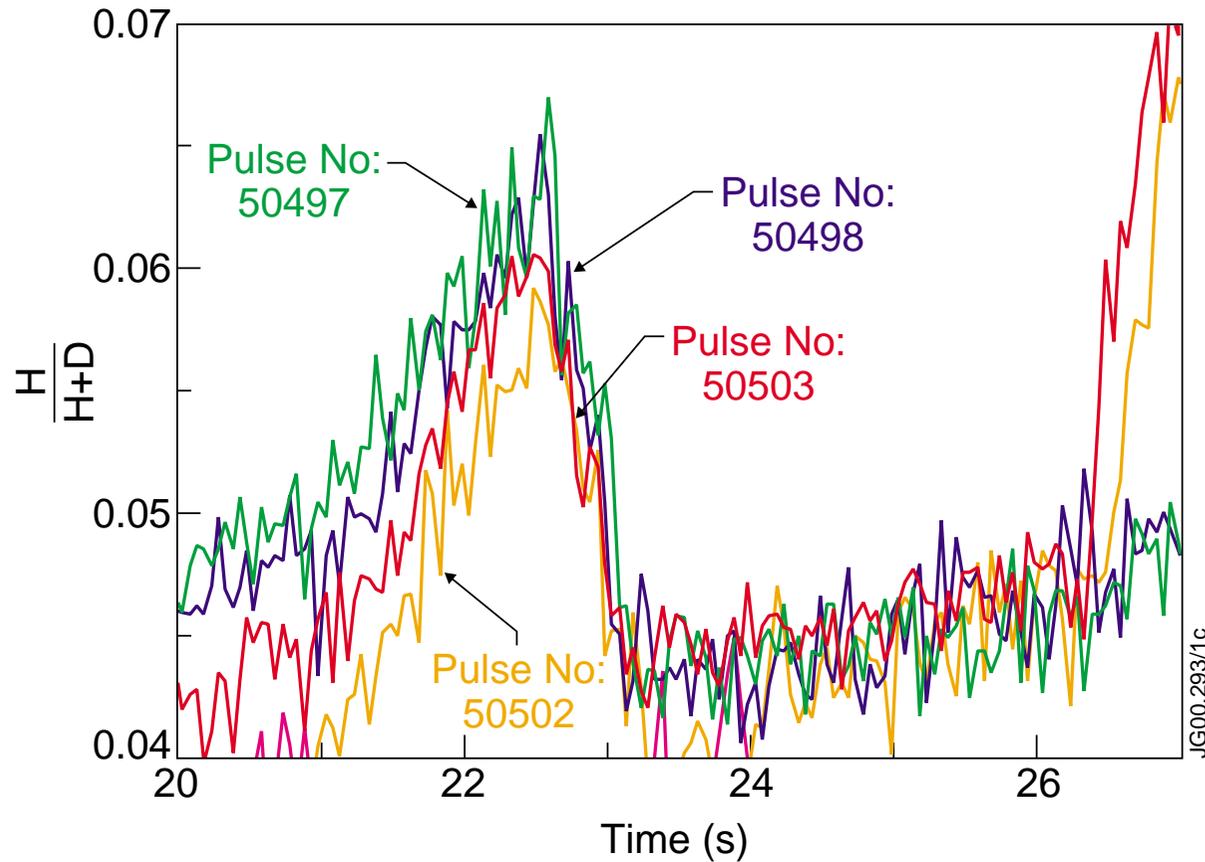

## Distribution function of hydrogen minority in Pulse No: 50502

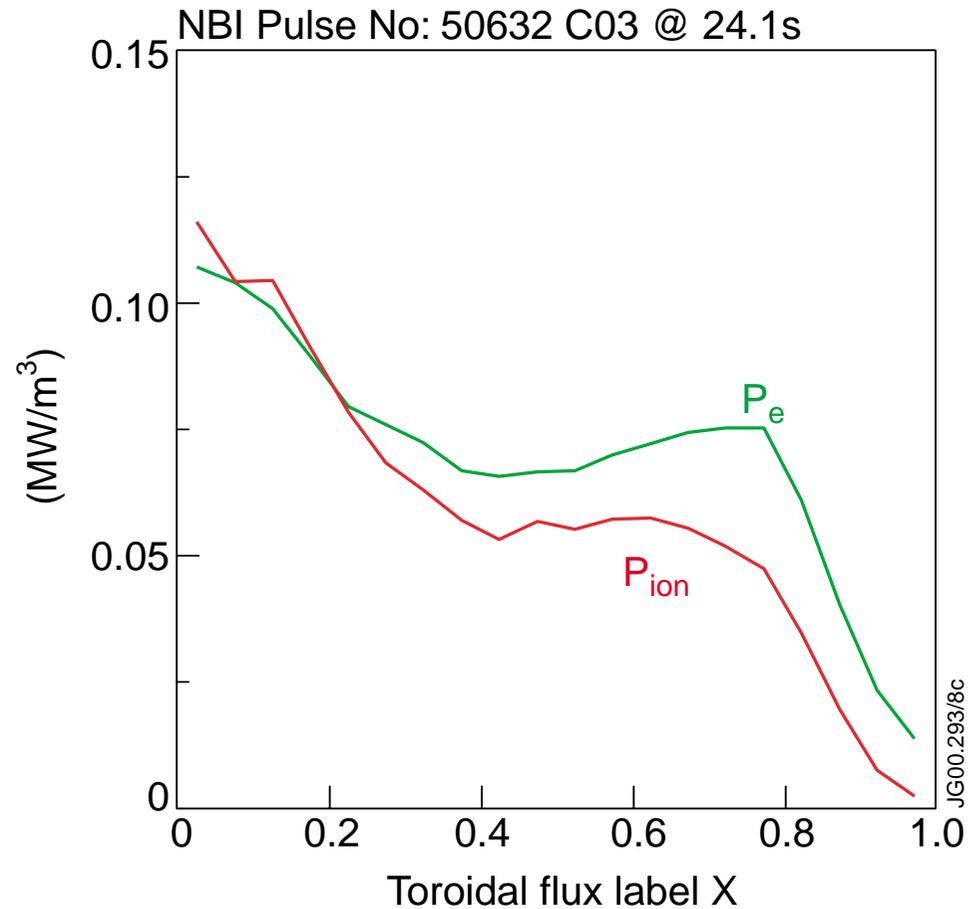

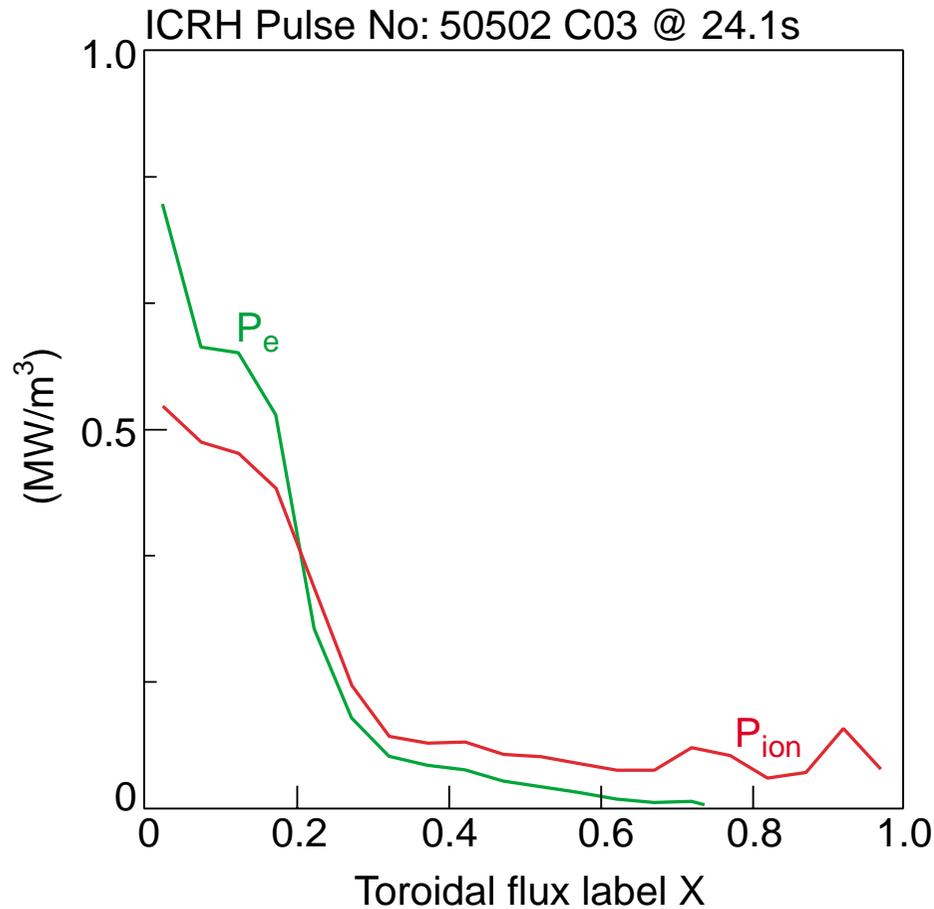

$n_{\text{H}}/n_{\text{e}} \approx 1\text{-}2\%$  in approximate agreement with measurements

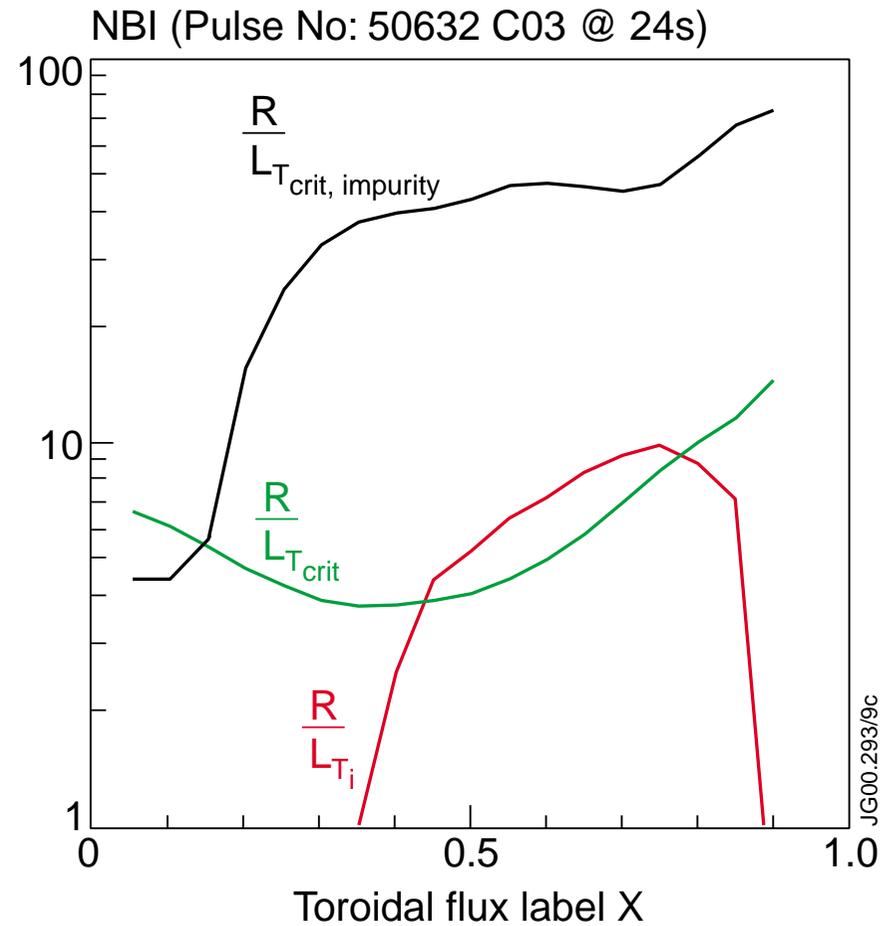

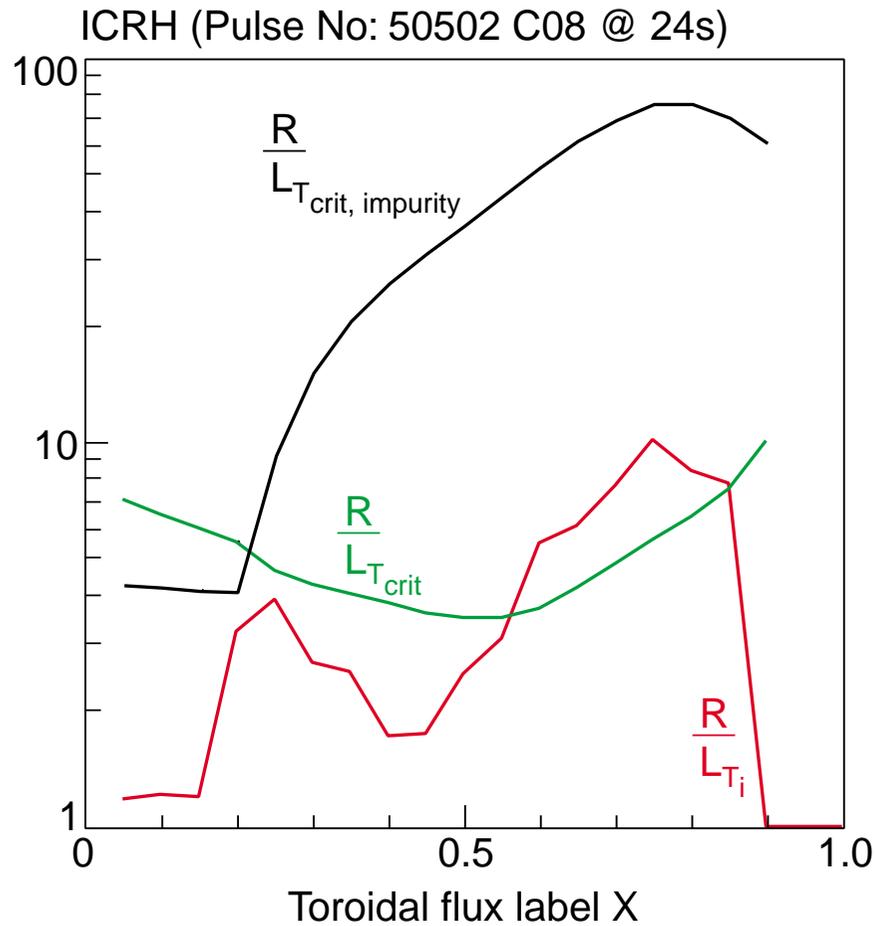

## H Concentration in the edge increases in time

# ICRH Heating power deposition to thermal plasma can simulate alpha heating

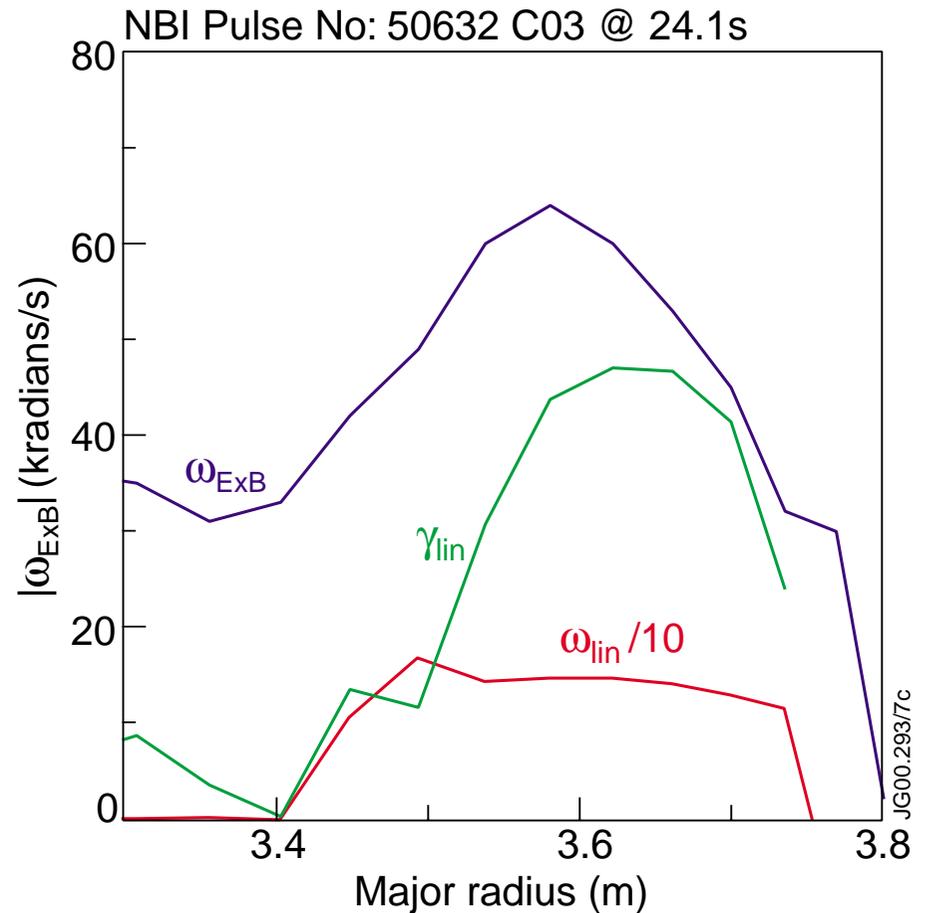

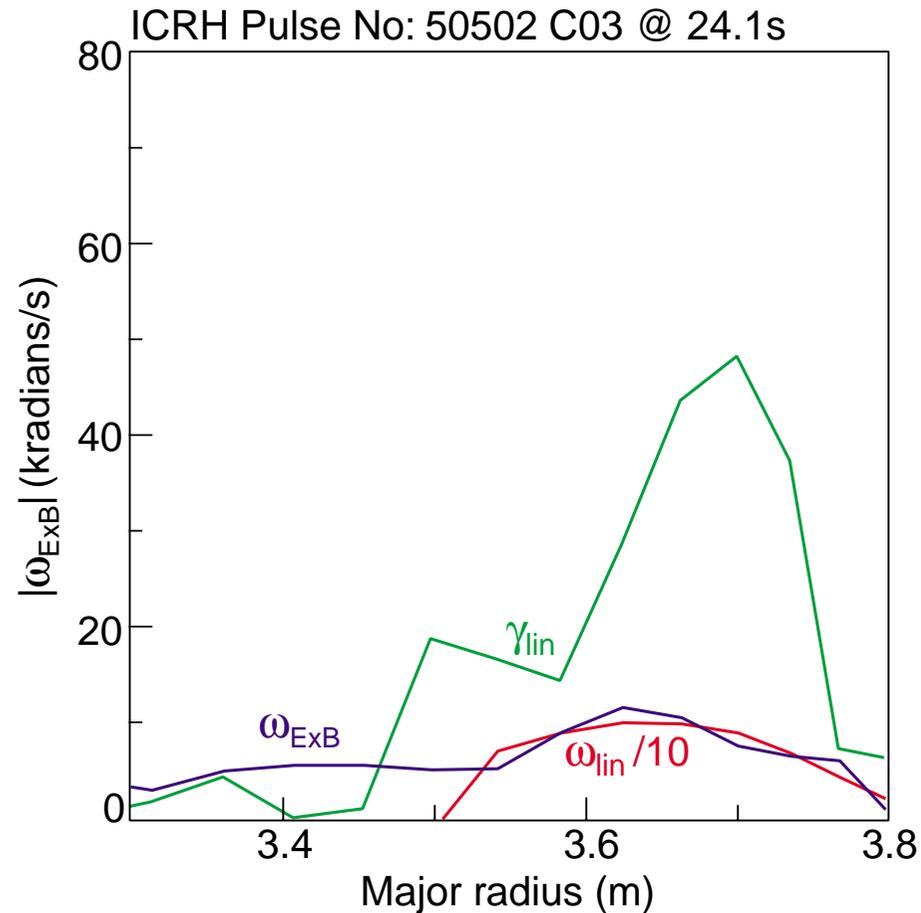

# Ion temperature gradient near the critical value at mid radius

JG00.293/9c

# Microturbulence growth rate, frequency and flow rate

Turbulence suppression ratio  $\omega_{ExB} / \gamma_{lin}$  small for ICRH, large for NBI

## Discussion

The turbulence suppression ratio  $\omega_{\text{ExB}} / \gamma_{\text{lin}}$  appears to be paradoxically small for ICRH plasmas

### Candidate explanations:

- $\omega_{\text{ExB}} / \gamma_{\text{lin}}$  is not a good indicator of microturbulence and transport suppression
- $V_{\text{Pol}}$  is larger than  $V_{\text{neoclassical}}$  and thus  $\omega_{\text{ExB}}$  is larger
- $\gamma_{\text{lin}}$  is not a good indicator of the amount of microturbulence and transport

## Future plans

Improve the ITG analysis to include non-linear effects, TEM branch, etc

Continue the experiment at higher heating power to produce plasmas with more reactor relevant conditions and lower torque from the diagnostic NBI

Apply theories of ICRH-induced rotation
